

LAB 4 | Automated IAM User Provisioning & RBAC

Identity & Access Management Portfolio | Jovar McNamee

Project overview

A simulated corporate identity-management project focused on user provisioning, Active Directory security groups, role-based access control (RBAC), and PowerShell-assisted administration. This document describes the lab workflow and distinguishes documented lab context from results requiring screenshot verification.

Lab environment

Windows Server 2022; Active Directory Domain Services; PowerShell; VMware Workstation Player; domain **jmc-local**; domain controller **JMC-DC01**. All users and roles are fictional lab identities.

Objectives

Create and manage user identities, align users to job-based security groups, reduce direct permission assignments, verify memberships, and document administrative changes for auditability.

IAM workflow

1. Define the employee identity, department, and access requirements.
2. Create or update the Active Directory account using an approved administrative workflow.
3. Assign the user to role-appropriate security groups instead of granting ad hoc permissions.
4. Query the account and group memberships to validate intended access.
5. Record evidence and identify access that exceeds the role requirement.

Lab identities and groups

Test identities	Security groups referenced
David Williams (dwilliams)	GG-IT-HelpDesk
Sarah Miller (smiller)	GG-IT-Support
Emily Carter (ecarter)	GG-Privileged-IT-Admins
Michael Reed (mreed)	Domain Users

Note: This table lists lab identities and groups, not a one-to-one mapping of users to groups. Confirm assignments against the original command outputs.

Example verification commands

```
Get-ADUser -Identity dwilliams -Properties MemberOf
Get-ADGroupMember -Identity "GG-IT-HelpDesk"
Get-ADGroupMember -Identity "GG-IT-Support"
```

These are reference commands for verification; this PDF does not claim that every command shown was executed in Lab 4.

Security controls demonstrated

Role-based group assignment, least-privilege design, account lifecycle administration, access verification, and auditable identity-management practices.

Evidence status & next steps

The project workflow and lab environment are documented. Original Lab 4 screenshots, provisioning script, and command outputs have not been included or independently verified in this report. Add only screenshots showing successful provisioning, group membership, and verification before presenting specific automation outcomes as proven.

Portfolio summary

Built a Windows Server Active Directory IAM lab workflow for identity provisioning and RBAC, with PowerShell-based verification steps and emphasis on least-privilege group membership. Supporting execution evidence is pending.
